

Supplemental Information: Campus-Level Propensity Scores for Matched Campuses (Web Only)

This supplemental information to the 2014-15 Texas Charter Authorizer Accountability Report is available online only. It includes detailed matching procedures used in the analysis, as well as the propensity score and the difference in the propensity score between each open-enrollment charter school campus included in the aggregate outcomes analyses and each matched traditional public school campus.

Methodological Detail

Texas Education Code (TEC) 12.1013(b) (4) required a comparison of charter schools by authorizer type with matched traditional campuses. The Request for Proposals (RFP) issued by the Texas Education Agency (TEA) requested the vendor to use a statistical matching procedure to identify traditional public school campuses that resemble charter school campuses based on publically available school characteristics, such as the ethnic composition of the campus, and the percentage of students who participate in supplemental programs that serve the needs of certain subgroups. Importantly, the intent of the matching procedure specified in the RFP is *not* to produce inferences about the relative effectiveness of charter school campuses compared to matched traditional public school campuses but, rather, to select traditional public school campuses that have similar student enrollment profiles in order to generate comparative descriptive statistics for several measures of campus performance.

The matching procedure is not being used in this manner because matching procedures are designed to estimate a treatment effect associated with some treatment condition ($D=1$, or the campus is a charter school campus) by constructing a counterfactual condition among non-treated units ($D=0$, or the school is a traditional public school campus) and comparing differences in some outcome between the treated units and the matched non-treated units. Implicit to this is the requirement that a unit (i.e., a campus) could have been placed into the counterfactual condition.¹ However, for this project, because matching is performed at the campus-level, the counterfactual (i.e., a traditional public school campus that resembles a charter school campus) is an unrealizable condition even after balancing on all available covariates: a traditional public school campus cannot be a charter school campus, nor can a charter school campus be a traditional public school campus.²

¹ Or, as Rosenbaum and Rubin (1983) stipulate, every unit should have a non-zero probability of being in either condition.

² It is possible, however, to assess the impact of attending a charter school campus on student outcomes using student-level records, but it is beyond the scope of this project. For instance, with student-level records, in Rapaport et al. (2014), students who attended a charter school campus were compared against matched students who did not attend a charter school campus, but who attended a school that was a feeder to new charter school campuses.

Keeping this in mind, we used propensity scores to identify “demographic peer” traditional public school campuses for each charter school campus.³ We did not use lagged outcome measures in the propensity score algorithm.⁴ In the previous 2012-13 Charter Authorizer Report published by TEA, 40 matched traditional public school campuses were selected for each charter school campus with no documented constraints imposed on the similarity between the matched and charter campuses based on each campus’ propensity score.⁵ We imposed two constraints on the selection of campuses with this procedure. First, we will only select traditional public school campus matches with a propensity score within 0.2 standard deviations of each charter school campus. Second, we will impose a constraint on the maximum number of traditional campuses (N=10) matched to each charter school campus based on discussions with TEA staff to limit the number of matches to a sufficient amount.

To identify measurably similar traditional public school campuses, the research team used nearest neighbor matching (NNM) in conjunction with a propensity score and a caliper of 0.2 standard deviations to find the *N* most similar traditional public school campuses to charter school campuses. This method is performed in two stages, following the procedures and notation of Becker and Ichino (2002):

Step 1: Fit a logistic regression:

$$\Pr(D_i = 1 | X_i) = \Phi\{h(X_i)\} \quad (1)$$

Where Φ is the propensity score, and $h(X_i)$ is a vector of 2014–15 campus-level (*i*) covariates.

The following campus-level covariates were included in the logistic regression to estimate the propensity score:

- Campus enrollment type (e.g., elementary, middle, or secondary)
- Student enrollment count
- Percentage of historically underrepresented racial minorities (Hispanic and Black students)
- Percentage of economically disadvantaged students
- Percentage of students receiving Special Education services
- Average years of experience of teachers
- Student mobility rates
- Percentage of students who are ELLs
- Percentage at-risk

³ This approach is not dissimilar to the use of propensity score matching to identify “fiscal peers” in the Financial Allocation Study of Texas (FAST). The appendix describing the rationale and implementation of this approach is can be found at <http://www.txsmartschools.org/pdf/2014/fast-2014-methodology.pdf>.

⁴ This is because we are attempting to find demographic peers for descriptive purposes, not matched comparison schools to generate quasi-experimental estimates of the impact of attending a charter school campus on student outcomes. Including lagged outcome measures in the propensity score model may unintentionally mislead the report’s audience into the belief that the intention of the comparisons between charter school campuses and matched traditional public school campuses is to make inferences about the contribution of a charter school to students’ academic performance, since the inclusion of lagged outcomes measures is designed to account for pre-intervention characteristics that may influence the placement into the treatment group. Additionally, in using the prior year’s performance data as a part of the matching process, we may drop out newer charter school campuses that do not have data available for these performance measures.

⁵ The FAST study uses a similar criterion for selecting peer campuses and districts, though, in the first stage, they use a caliper of two standard deviations of a propensity score to select up to 40 matched campuses within this band. If fewer than 40 campuses are available within this band, all campuses within the respective stratum are selected.

In TAPR, both the campus-level student mobility rate and the average years of experience of teachers have missing values. The missing values for student mobility rates are attributable to new campuses for which the mobility cannot be calculated between 2013–14 and 2014–15. The reason for the missing values for teachers’ experience levels is currently unknown, but appears to be a function of whether the campus has dedicated staff that are assigned to the campus, as opposed to sharing the staff with other schools within the district. To retain these variables in the matching procedure, and to incorporate information about the pattern of missingness between charter campuses and traditional public schools, dummy variable imputation will be used so that these variables can still be included in the propensity score algorithm and that campuses that are missing this information are not discarded. See [Stuart \(2011\)](#) for advocacy of this method for the estimation of propensity scores.

Step 2: Find the nearest neighbors for each charter school campus with in a 0.2 standard deviation caliper up to 10 matches

$$C(i) = \|p_i - p_j\| \leq c_{.2\sigma} \tag{2}$$

In (2), we selected the non-treated units (j) that satisfy the condition $(C(i)) \|p_i - p_j\| \leq c_{.2\sigma}$. In other words, we selected the traditional public school campuses with the smallest with a propensity score within 0.2 standard deviations of the charter school campus. Matched campuses, and the propensity score, are be presented in the supplemental information in this document.

All descriptive analyses were performed between charter school campuses and matched traditional public school campuses, with unmatched, traditional public schools discarded from the analytic dataset. All charter school campuses, however, will be retained.⁶

Residential Treatment Facility campuses, DAEP campuses, and JJAEP campuses (charter schools and traditional schools) were excluded from the matching process and the analytic dataset that was used to report aggregate campus academic performance metrics for charter school campuses and their matched traditional public school campuses.

⁶ These methodological choices will not, necessarily, produce complete balance with trivial, insignificant differences between charters and their matched peers on the covariates included in the algorithm. For instance, small numbers of eligible campuses from a given authorization type pool may be more imbalanced compared to a pool of charter campuses with a large number of eligible campuses. This imbalance may be exacerbated since charter school campuses (i.e., the treatment condition) with poor matches that did not resemble other charter campuses were retained in the analysis sample: put more formally, the common support condition was only imposed on traditional campuses, and not charter school campuses

Propensity Scores for Charter School Campuses and each of their matched Traditional Public School Campuses
