

Associations between Health-Related Fitness
and Academic Achievement (2011 to 2014)

A Report from the Texas Youth Fitness Project

Kelly Allums-Featherston, The Cooper Institute
Yang Bai, Iowa State University
Gregory Welk, Iowa State University

Overview and Summary of Key Findings

The promotion of physical activity and physical fitness in youth is important to reduce the risk of chronic diseases later in life. There is also increasing evidence to support associations between physical activity / physical fitness and indicators of academic achievement. This report summarizes associations between health-related physical fitness and academic achievement using four years of data from the Texas Education Association. The focus of these analyses was on two specific health-related fitness assessments [aerobic capacity (AC) and body composition (BC)]. The associations were examined using two different analytic techniques to provide a more comprehensive evaluation.

Spearman correlations were computed by age, gender and year to examine the overall relationships with academic achievement. The associations varied by fitness test and academic test (as well as by gender and grade). Partial correlations controlling for key school level factors (socio-economic status, percent minority, and school enrollment) revealed weak correlations (i.e., < 0.20) for most comparisons. Consistent with previous findings, the associations were strongest in middle school students (6th to 8th graders). Stronger associations were generally found for body composition, compared to aerobic capacity. When results were stratified by level of Healthy Fitness Zone (HFZ) achievement (low, medium and high), schools with higher levels of HFZ achievement tended to have higher levels of academic achievement but results varied by test, grade and age. Overall, body composition had a stronger association with math achievement and associations were stronger in middle school grades than elementary grades. Similar analysis was applied to data from 2011 and 2014 to evaluate the impact of fitness achievement on school attendance. AC had moderate associations with attendance, even after controlling for several confounders. When results were stratified by level of AC HFZ achievement, schools with high levels of HFZ achievement tended to have higher attendance rates. No association was found between BC and attendance.

The results of the analyses provide continued evidence supporting links between health-related fitness and academic achievement (as well as modest associations with attendance). However, the varied relationships make it difficult to draw definitive conclusions. Additional research with individual measures offers potential to better understand the relationships.

Association between Fitness and Academic Achievement

Methods and Results

The data from the Texas Youth Fitness Project make it possible to systematically examine health-related fitness and links with academic achievement in the state of Texas. This report summarizes the associations between two specific health-related fitness assessments (Aerobic Capacity-AC and Body Composition-BC) and two academic assessments (math and reading) for four different years of data collected by the Texas Education Association (2010/2011, 2011/2012, 2012/2013, and 2013/2014). The fitness data were screened using established procedures to ensure that results from individual schools provided generalizable results by both grade and gender.¹ This resulted in a sample of 2,761 elementary schools and 1,530 middle schools in 2011, 2,749 elementary schools and 1,173 middle schools in 2012, and 2,532 elementary and 1,073 middle schools in 2013. The 2014 sample included for comparison with AC data are 1,314 elementary schools and 580 middle schools, whereas the 2014 sample included for comparison with BC data are 2,501 elementary schools and 1,107 middle schools² The association between AC, BC and attendance was also studied with data from 2011, 2012, 2013, and 2014. A similar analytical approach was applied to fitness and attendance data.

The evaluation focused on the associations between percent of students that achieved the established FITNESSGRAM® Healthy Fitness Zone® (HFZ) with the percent of students that achieved Level II Satisfactory--Phase-in 1 for the reading and math standards test. The TAKS test was administered to students in 2011, while the STAAR test was used for the majority of students in 2012, 2013, and 2014. Though the tests are similar, direct comparisons of achievement between the two tests should not be made. Student achievement from 4th to 8th grade were included in this report, as there were available grade level data on both academic achievement and physical fitness (e.g., 5th grade math and reading with 5th grade aerobic capacity and body composition). The “End of Course” (EOC) exam data from the STAAR test are available for students in grades 9th to 12th grade. However, students take EOC exams based on curriculum that has been completed rather than identified grade level (e.g., 9th and 10th grade students could take English I). Due to the inability to directly link academic and fitness data by grade, analyses of associations between academic and fitness data were not completed for grades 9th to 12th grade.

Two specific analyses were conducted for each year of data. One set of analyses examined correlations between % of youth achieving the age specific HFZ and the % of youth achieving the age specific academic standards. Spearman correlations were used to deal with data that was not normally distributed. Analyses were conducted with and without controlling for other school level factors in order to determine the impact of these variables on the results. The “partial” correlations that control for school level variables provide a more appropriate (and more conservative) view of the associations since it removes shared variance due to factors such as socio-economic status.

¹ Methods used to screen the data were summarized in a separate report documenting the levels and patterns of health-related fitness achievement based on the 2011, 2012, 2013, and 2014 FITNESSGRAM data.

² 2014 AC data includes only data submitted to the Texas Education Agency (TEA) via the Physical Fitness Assessment Initiative (PFAI; approximately 2,400,000 youth; 2/3 of Texas students), data submitted using the FITNESSGRAM (FG) version 10 software were excluded to prevent comparisons of AC data using different health-related fitness standards and/or calculations. 2014 BC data includes all data submitted to the TEA regardless of submission channel (i.e., PFAI or FG), as the same health-related standards were able to be applied for all BC data.

Association between Fitness and Academic Achievement

The other set of analyses used more sophisticated general linear models to examine the relationship between health-related fitness and academic achievement. For these analyses, both AC and BC were categorized into tertiles (i.e., high, medium, and low AC and BC achievement groups), respectively. Least square means of math and reading achievement were reported by three fitness levels after adjusting for the school demographic characteristics (i.e., SES, minority rate, and school size). These analyses provide more easily interpretable findings since they directly compare schools with high, medium and low levels of school level fitness achievement on indicators of academic achievement.

Some key summaries are below:

i. Fitness Associations with Math, Reading

1. Results from Spearman Correlation Analyses:

Spearman correlations were computed by age, gender and year to examine the overall relationships. The association between health-related fitness and academic achievement varied by fitness test and academic test (as well as by gender and grade). Correlations were low to moderate with higher correlations generally noted for body composition (range: 0.17 to 0.50) than aerobic capacity (range: 0.11 to 0.47). Partial correlations controlling for key school levels factors (socio-economic status, percent minority, and school enrollment) reduced the correlations for both BC (range: 0.02 to 0.19) and AC (range: 0 to 0.16). This is not surprising since it is known that SES and other school characteristics can influence both health-related fitness and academic achievement. Associations were consistently higher for older middle school students (6th to 8th grade). Details on the findings for each year are summarized below:

- 2011
 - Girls: Spearman correlations ranged from 0.11 to 0.39 for AC and from 0.2 to 0.48 for BC ([Figure 1](#)). The corresponding ranges for the partial correlations were 0 to 0.12 and 0.06 to 0.19, respectively ([Figure 2](#)). Higher correlations were consistently reported for older youth.
 - Boys: Spearman correlations ranged from 0.12 to 0.45 for AC and from 0.17 to 0.45 for BC ([Figure 3](#)). The corresponding ranges for the partial correlations were 0 to 0.12 and 0.02 to 0.11, respectively ([Figure 4](#)). Higher correlations were consistently reported for older youth.
- 2012
 - Girls: Spearman correlations ranged from 0.18 to 0.39 for AC and from 0.26 to 0.48 for BC ([Figure 10](#)). The corresponding ranges for the partial correlations were 0.02 to 0.11 and 0.03 to 0.12, respectively ([Figure 11](#)). Higher correlations were consistently reported for older youth.
 - Boys: Spearman correlations ranged from 0.18 to 0.41 for AC and from 0.26 to 0.47 for BC ([Figure 12](#)). The corresponding ranges for the partial correlations were 0 to 0.14 and 0 to 0.09, respectively ([Figure 13](#)). Higher correlations were consistently reported for older youth.
- 2013

Association between Fitness and Academic Achievement

- Girls: Spearman correlations ranged from 0.18 to 0.42 for AC and from 0.30 to 0.48 for BC ([Figure 19](#)). The corresponding ranges for the partial correlations were 0 to 0.08 and 0.08 to 0.17, respectively ([Figure 20](#)). Higher correlations were consistently reported for older youth.
- Boys: Spearman correlations ranged from 0.22 to 0.43 for AC and from 0.26 to 0.48 for BC ([Figure 21](#)). The corresponding ranges for the partial correlations were 0.03 to 0.16 and 0.02 to 0.13, respectively ([Figure 22](#)). Higher correlations were consistently reported for older youth.
- 2014
 - Girls: Spearman correlations ranged from 0.20 to 0.44 for AC and from 0.28 to 0.50 for BC ([Figure 28](#)). The corresponding ranges for the partial correlations were 0.02 to 0.14 and 0.07 to 0.15, respectively ([Figure 29](#)). Higher correlations were consistently reported for older youth.
 - Boys: Spearman correlations ranged from 0.20 to 0.47 for AC and from 0.26 to 0.45 for BC ([Figure 30](#)). The corresponding ranges for the partial correlations were 0 to 0.13 and 0 to 0.16, respectively ([Figure 31](#)). Higher correlations were consistently reported for older youth.

2. Results from General Linear Models.

General Linear Models were used to compare schools with high, medium and low levels of health-related fitness achievement. Results showed differences between high and low levels of achievement but results again varied by test, grade and age. Specific findings for each year are summarized below (separately for girls and boys).

In 2011, among girls

- Findings for Aerobic Capacity:
 - 4th, 6th and 7th grade girls who were in the high AC achievement schools had significantly higher math achievement rates than their peers from low AC achievement schools ([Figures 5a, 7a, 8a](#), respectively).
- Findings for Body Composition (BC):
 - 5th, 6th and 7th grade girls who were in the high and medium BC achievement had significantly higher math and reading achievement rates than their peers from low BC achievement schools ([Figure 6a, 7a](#), and [8a](#) respectively).
- 7th grade girls who were in high BC achievement schools had significantly higher math and reading achievement rates than their peers from low BC achievement schools ([Figure 8a](#)).

In 2011, among boys

- Findings for Aerobic Capacity (AC):
 - 6th and 8th grade boys who were in the high AC achievement schools had statistically significant higher math achievement rates than their peers from medium AC achievement schools ([Figures 7b](#) and [9b](#), respectively).

Association between Fitness and Academic Achievement

- 8th grade boys who were in the high AC achievement schools had statistically significant higher math achievement rates than their peers from low AC achievement schools (Figure [9b](#)).
- Findings for Body Composition (BC):
 - 6th grade boys who were in the high BC achievement schools had statistically significant higher math and reading achievement rates than their peers from low BC achievement schools (Figure [7b](#)).
 - 8th grade boys who were in the high BC achievement schools had statistically significant higher math achievement rates than their peers from medium BC achievement schools (Figure [9b](#)).

In 2012, among girls

- Findings for Aerobic Capacity:
 - 8th grade girls who were in the high AC achievement schools had statistically significant higher math achievement rates than their peers from medium and low AC achievement schools, respectively (Figure [18a](#)).
- Findings for Body Composition (BC):
 - 5th to 8th grade girls who were in the high BC achievement schools had statistically significant higher math achievement rates than their peers from low BC achievement schools (Figures [15a](#), [16a](#), [17a](#), [18a](#)).
 - 7th and 8th grade girls who were in the high BC achievement schools also had statistically significant higher math achievement rates than their peers from medium BC achievement schools (Figure [17a](#) and [18a](#)).

In 2012, among boys

- Findings for Aerobic Capacity:
 - 7th grade boys who were in the high AC achievement schools had statistically significant higher math achievement rates than their peers from medium AC achievement schools (Figures [17b](#)).
 - 7th and 8th grade boys who were in the high AC achievement schools had statistically significant higher reading achievement rates than their peers from medium AC achievement schools (Figures [17b](#) and [18b](#), respectively).
 - 7th grade boys who were in the medium AC achievement schools had statistically significant higher reading achievement rates than their peers from low AC achievement schools (Figure [17b](#)).
- Findings for Body Composition (BC):
 - 6th and 7th grade boys who were in the medium BC achievement schools had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [16b](#) and [17b](#)).

Association between Fitness and Academic Achievement

- 7th grade boys who were in the high BC achievement schools had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [17b](#)).
- 6th grade boys who were in the high BC achievement schools had statistically significant higher math achievement rates than their peers from low and medium BC achievement schools, respectively (Figure [16b](#)).

In 2013, among girls

- Findings for Aerobic Capacity:
 - There were no significant achievement differences for any grades when stratified by AC achievement.
- Findings for Body Composition (BC):
 - 4th and 6th grade girls who were in the medium BC achievement schools had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [23a](#) and [25a](#)).
 - 5th and 7th grade girls who were in the high BC achievement schools had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [24a](#) and [26a](#)).
 - 4th and 7th grade girls who were in the medium and high BC achievement schools had statistically significant higher math achievement rates than their peers from low BC achievement schools (Figure [23a](#) and [26a](#)).
 - 8th grade girls who were in the high BC achievement schools had statistically significant higher math achievement rates than their peers from medium BC achievement schools (Figure [27a](#)).

In 2013, among boys

- Findings for Aerobic Capacity:
 - 6th grade boys who were in the high AC achievement schools had statistically significant higher reading achievement rates than their peers from low AC achievement schools (Figure [25b](#)).
 - 7th grade boys who were in the medium AC achievement schools had statistically significant higher reading achievement rates than their peers from low AC achievement schools (Figure [26b](#)).
- Findings for Body Composition (BC):
 - 6th and 7th grade boys who were in the medium and high BC achievement schools had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [25b](#) and [26b](#)).
 - 6th grade boys who were in the high BC achievement schools had statistically significant higher math achievement rates than their peers from low BC achievement schools (Figure [25b](#)).

In 2014, among girls

- Findings for Aerobic Capacity:

Association between Fitness and Academic Achievement

- 5th and 6th grade girls who were in high AC achievement schools had statistically significant higher reading achievement rates than their peers from low AC achievement schools, respectively (Figure [33a](#) and [34a](#)).
- Findings for Body Composition (BC):
 - 5th, 6th, 7th grade girls who were in the high and medium BC achievement schools had statistically significant higher math and reading achievement rates than their peers from low BC achievement schools, with higher rates for reading from medium to low schools (Figures [33a](#), [34a](#), [35a](#)).
 - 8th grade girls who were in the high and medium BC achievement schools also had statistically significant higher reading achievement rates than their peers from low BC achievement schools (Figure [36a](#)).

In 2014, among boys

- Findings for Aerobic Capacity:
 - 6th grade boys who were in the high and medium AC achievement schools had statistically significant higher reading achievement rates than their peers from medium and low AC achievement schools respectively, with higher rates in math at the medium AC achievement schools compared to the low AC achievement schools (Figure [34b](#)).
- Findings for Body Composition (BC):
 - 6th and 7th grade boys who were in the high and medium BC achievement schools had statistically significant higher math and reading achievement rates than their peers from low BC achievement schools respectively (Figure [34b](#), [35b](#)).

ii. Fitness Associations with Attendance

1. Results from Spearman Correlation Analysis

Spearman correlations were computed by gender and year to examine the overall relationships. The association between health-related fitness and academic achievement varied by gender but were consistent across 2011 and 2014. Correlations were moderate between AC and attendance among boys (0.43 in 2011, 0.46 in 2012, 0.43 in 2013, and 0.34 in 2014) who tended to have higher correlations than girls (0.32 in 2011, 0.34 in 2012, 0.32 in 2013, and 0.26 in 2014). Partial correlations controlling for key school levels factors (socio-economic status, percent minority, and school enrollment) did not change the association for both boys (0.42 in 2011, 0.44 in 2012, 0.42 in 2013, and 0.30 in 2014) and girls (0.31 in 2011, 0.32 in 2012, 0.31 in 2013, and 0.22 in 2014).

2. Results from General Linear Models.

A significant association was only found in AC and attendance, thus General Linear Models were only used to compare schools with high, medium and low levels of AC health-related fitness achievement. Results showed that schools with higher AC health-related fitness achievement had significantly higher attendance rates. These patterns were consistent for both boys and girls. However, no patterns were evident when attendance was related to body composition. See Figures [37](#), [38](#), [39](#), and [40](#).
